

PolicyReplay: Misconfiguration-Response Queries for Data Breach Reporting

Daniel Fabbri*, Kristen LeFevre*, Qiang Zhu+ *Electrical Engineering and Computer Science, University of Michigan *Computer and Information Science, University of Michigan - Dearborn

Motivation:

- Databases use access control policies to restrict access
- Unfortunately, these access policies are complex
- · As a result, the policies are sometimes misconfigured
- · Users may read or modify data inappropriately
- Recent legislation increases requirements to report breaches
- American Recovery and Reinvestment Act of 2009 increases HIPAA reporting rules for hospitals

Preliminaries:

The database is a transaction-time backlog DB

•The database stores a log of all operations executed on the DB

Problem:

Find operations that were affected by the misconfiguration

Misconfiguration-Response (MR) Queries

Returns all queries that were substantively affected by the misconfiguration

Naïve Solution:

- Go back in time to when the misconfiguration started 1.
- 2. Apply the correct access control policies
- 3. Replay all operations on a copied database
- Compare query results under the old and new policies 4
- 5. If the results differ, then the query is suspicious

Weaknesses:

- Replays all operations
- Copies the entire database

PolicyReplay Optimizations

1. Pruning: Reduce the number of operations re-executed

Static Pruning (Queries Only):

- Delta Expressions: Change in visibility of a row due to the policy misconfiguration
- Analyze the query's selection condition Determine, without re-executing, that the query is not suspicious
- Delta Tables (With Updates): For each table, stores the row-wise difference
- between the old policy and the new policy.

Pruning Condition for an Operation:

- 1. Statically prunable
- 2. Does not use rows from the delta tables

Re-Execution: Reduce re-execution costs

Re-Execution:

When an operation cannot be pruned, the operation must be re-executed

Partial Re-Execution:

Determine mid-execution that an operation is unsuspicious

Simultaneous Re-Execution:

Execute the guery on the old policy and new policy simultaneously (shared computation)

s R R s Partial Re-Execution Query $\sigma_{\mathsf{Told}}(\mathsf{T}^{\mathsf{t}})$ - $\sigma_{\mathsf{Tnew}}(\widehat{\mathsf{T}}^{\mathsf{t}})$ $\sigma_{T_{new}}(\hat{T}^t) \cap \sigma_{T_{old}}(T^t)$ $\sigma_{T_{new}}(\widehat{T}^t) - \sigma_{T_{old}}(T^t)$ $\sigma_{Rold}(R^t) - \sigma_{Rnew}(\hat{R}^t)$ $\sigma_{S_{old}}(S^t) - \sigma_{S_{new}}(\hat{S}^t)$ $\sigma_{\mathsf{R}_{\mathsf{new}}}(\hat{\mathsf{R}}^{\mathsf{t}})\cap\sigma_{\mathsf{R}_{\mathsf{old}}}(\mathsf{R}^{\mathsf{t}})$ $\sigma_{\mathsf{S}_{\mathsf{new}}}(\widehat{\mathsf{S}}^{\mathsf{t}}) \cap \sigma_{\mathsf{S}_{\mathsf{old}}}(\mathsf{S}^{\mathsf{t}})$ $\sigma_{R_{new}}(\hat{R}^t) - \sigma_{R_{old}}(R^t)$ $\sigma_{S_{new}}(\hat{S}^t) - \sigma_{S_{old}}(S^t)$ Simultaneous Re-Execution - Combined Query Plan

Experimental Evaluation

Vary the following parameters: Size of the policy misconfiguration, operation selectivity, select to update ratio, size of the DB, the number of predicate attributes.

1% Policy Misconfiguration. 1% Selectivity, 250 K Rows, Predicate Attributes=1

10% Policy Misconfiguration

1% Selectivity, 250 K Rows, Predicate Attributes=1

Naive + Simul

Putting It All Together

- 1 Create empty delta tables
- 2. Replay all operations (no need to copy the DB)
- If the operation is prunable, skip. 3.
- Otherwise, re-create the DB from the old DB and 4 the delta tables.
- 5. Re-execute the operation
- a) Determine if a query is suspicious b) Update the delta tables

MR-Query Components

Results

- 1. Optimizations can reduce reporting time by up to an order of magnitude.
- 2. As the misconfiguration gets larger, the cost of re-executing with the optimizations increases.
- There exists a trade-off point when pruning plus delta tables is not efficient; rather, the naïve approach is better.
- 4. Simultaneous re-execution improves the performance of the naïve and optimized methods.
